The overall objective of this study was to investigate in the laboratory the feasibility of using saturated solar ponds for unmixing a brine of intermediate concentration into dilute and concentrated brine streams for salinity gradient energy conversion systems. This objective was accomplished by conducting experiments on laboratory saturated ponds using borax, potassium perchlorate, potassium nitrate, disodium phosphate and potassium alum. Results from ponds using borax, potassium nitrate and disodium phosphate conclusively demonstrated that saturated solar ponds can self-generate and self-maintain a stable density gradient. Moreover, these ponds reestablished stable density profiles after the ponds were externally mixed. Based on preliminary results, the residence time for unmixing of a brine of intermediate concentration into dilute and concentrated brine streams varies from a few days for the borax pond to about two weeks for the disodium phosphate pond, depending upon the characteristics of the individual saturated solution. Because of only a very small increase in the density of saturated solutions from 25 ° C to 90 ° C, the potassium perchlorate pond could not establish a stable density stratification.

The lipid bilayer is central to life, as all living organisms possess a lipid bilayer structure, thereby underlying the lipid bilayer principle of biomembranes. The lipid bilayer principle and its applications are the main theme of this new book series. This new series on bilayer lipid membranes (BLMs and liposomes) include invited chapters on a broad range of topics, from theoretical investigations, specific studies, experimental methods, to practical applications. Written for newcomers, experienced scientists, and those who are not familiar with these specific research areas, the Series covers all aspects of lipid bilayer investigations, both fundamental and applied. * Covers a broad range of topics ranging from theoretical research, specific studies, experimental methods, to practical applications * Authoritative timely reviews by experts in this field * Indispensable source of information for new scientists

Published by the American Geophysical Union as part of the Geophysical Monograph Series, Volume 94. The existence of double-diffusive convection and the associated, visually dramatic and dynamically significant salt fingers (as a molecular instability mechanism that can naturally arise in the ocean) was first recognized in the late 1950s. Since then, research in this area has increased almost exponentially, and new applications of the basic phenomenology continue to arise. At this time the importance of double-diffusive convection (DDC) has been recognized in fields as diverse as geophysics, astrophysics, metallurgy and chemistry as well as in the parent field—ocean physics. In each of these fields the small-scale, DDC phenomenology has been shown (or at least postulated) to be a critical driver for large, even global scale processes. Examples include DDC as a mechanism for maintaining the ocean thermocline and thus the global circulation pattern and DDC as a factor in convection of the Earth's mantle and at the core-mantle boundary.
