It is suggested that this decoupling results from an increase with speed in the extent to which the internal work of locomotion is powered by non-metabolic means, such as elastic strain energy and transfer of energy within and between body segments.

The world of static electricity involves invisible fields and forces produced by the presence of invisible build-up of invisible charges. The results are always visible while the causes are not. But with these simulations, the invisible becomes visible as you interact with the objects and observe their effects upon surrounding objects.

An electric motor doesn't produce its power in perceivable pulses like a two or four-stroke engine does. Each pulse of power from a petrol engine is an opportunity for the tyre to lose traction. Once lost, that traction is hard to grab hold of again, and whichever way you fix it, anything done is killing your momentum.

An electric locomotive is a locomotive powered by electricity from overhead lines, a third rail or on-board energy storage such as a battery or a supercapacitor . Electric locomotives with on-board fueled prime movers, such as diesel engines or gas turbines, are classed as diesel-electric or gas turbine-electric and not as electric locomotives, because the electric generator/motor combination serves only as a power transmission system .

When energy in a battery is used to power an electronic device, chemical energy is transformed into electrical energy, which moves along wires. Three more ways energy can be transferred are through light, sound, and heat. Energy can be transferred as light. Light energy is the only form of energy we can see.
